**Abstract:** The experiment was conducted at the Seed Laboratory of the Department of Agronomy, Bangladesh Agricultural University, Mymensingh during June 2010 to December 2011 to develop a suitable and low cost groundnut seed storage technology. Four storage container Polythene bag, Plastic pot, Tin container and Cloth bag and three initial seed moisture content (8%, 10% and 12%) were included in the present study to evaluate their effects on germination performance of groundnut seed. Experiment was arranged in completely randomized design with three replications. The highest germination performance was recorded from seeds stored at 8% initial seed moisture content (SMC) in polythene bags. The present study concludes that shelled groundnut seed could be stored safely from one rabi season to the next if stored in polythene bags after drying to 8% initial seed moisture content.

**Key words:** Groundnut, moisture content and storage container.

**Introduction**

Rapid loss of germination and vigour during storage under ambient condition is a major constraint in groundnut (*Arachis hypogaea* L.) production especially under tropical condition like Bangladesh. As oilseed, groundnut encounters rapid seed deterioration during storage. Rate of increase of seed moisture content depends on the type of storage container. The impermeable containers (non-porous) such as polythene bag, tin container etc. can keep seed moisture content at safer level than porous container. Research at Bangladesh Agricultural University, Mymensingh suggests that polythene bag is capable of maintaining the low moisture content of seed even when stored at high (60-80% RH) ambient relative humidity (Rahman *et al.*, 1994). On the other hand, if seeds are stored in shelled condition, it can save 60-70% volume. But experiment on the effect of different storage environment of shelled groundnut seed has not been conducted so far. So, there is a need to evaluate the performance of shelled and unshelled groundnut seed under variable storage environment. Considering the above facts and observation, the present research work, therefore, was undertaken with a view to develop suitable techniques for storage of groundnut seed to study the effect of storage container on groundnut seed quality and to determine the effect of seed moisture content and relative humidity on groundnut seed quality.

**Materials and methods**

The experiment was conducted during June 2010 through December 2011 to study the effect of storage environment on quality of groundnut seed at the Seed Laboratory, Department of Agronomy, Bangladesh Agricultural University (BAU), Mymensingh. Freshly, harvested seeds of groundnut cv. BINA badam4 was taken in four storage container (polythene bag, plastic pot, tin container and cloth bag) and three initial seed moisture content (8%, 10% and 12%) were included in the study. The groundnut seed was properly sun dried and the shelling of groundnut seed was done manually with care and safety to avoid mechanical injury of shelled seed. Completely randomized design was used with three replications. The seed quality parameters such as seed moisture content, germination (%), and vigour index were recorded at start of storage and also at 40, 80, 120 and 200 days after storage (DAS). The following parameters were measured by standard rules

(ISTA, 2003). The number of seedlings emerged each day were counted up to 15 days after sowing. Data analysis was done following analysis of variance technique adopting the design followed in each experiment using computer package programs (ANOVA) MSTAT-C. Mean comparison was done following Duncan’s Multiple Rang Test (DMRT) at 5% level of significance.

**Results and Discussion**

**Seed moisture content (SMC):** Seeds stored at different storage container showed significant variation in their moisture content at each of the testing dates during the storage period. In 2010, the moisture content of seeds stored in polythene bag were 10.45%, 10.78%, 11.24%, 11.47% and 12.01% at 40, 80, 120, 160 and 200 days after storage (DAS) while those stored at cloth bag were 11.90%, 14.22%, 14.71%, 14.77% and 14.79%, respectively. In 2011, the moisture content of seeds stored in polythene bag were 10.48%, 10.79%, 11.26%, 11.48% and 12.03% at 40, 80, 120, 160 and 200 DAS while those stored in cloth bag gained 11.92%, 14.24%, 14.73%, 14.78%, 14.81%, respective (Fig. 1).

**Fig 1.** Effect of storage container on moisture content of shelled groundnut seed at different days after storage in 2010 and 2011.

**Fig 2.** Effect of initial SMC on moisture content of shelled groundnut seed at different days after storage in 2010 and 2011.

The initial SMC had significant effect on moisture content of groundnut seed at each of the observation dates during the storage period from June to December in 2010 and

2011. In 2010, the seeds stored at 8% initial SMC attained moisture content of 9.33%, 10.22%, 10.72%, 10.91% and 11.35% at 40, 80, 120, 160 and 200 DAS while those stored at 12% initial SMC attained at 12.59%, 13.30%, 13.72%, 13.86% and 14.30%, respectively. In 2011, the seeds stored at 8% initial SMC gained moisture content of 9.35%, 10.23%, 10.73%, 10.92% and 11.37% while those values for 12% initial SMC were 12.62%, 13.31%, 13.74%, 13.88% and 14.33% SMC, respectively (Fig. 2)

The interaction effect of storage container and initial SMC on moisture content of groundnut seed was also

statistically significant. In 2010, the moisture content of seeds stored at 8% initial SMC in polythene bag obtained 8.47%, 8.84%, 9.31%, 9.58% and 10.12% at 40, 80, 120, 160 and 200 DAS while those stored at 12% initial SMC in cloth bags had 12.70%, 14.62%, 14.92%, 14.98% and 15.00% SMC. In 2011, seeds stored at 8% initial SMC in polythene bag reached seed moisture content of 8.49%, 8.85%, 9.32%, 9.59% and 10.13% at 40, 80, 120, 160 and 200 DAS, respectively while those stored at 12% initial SMC in cloth bag exhibited 12.72%, 14.64%, 14.94%, 15.00% and 15.03%, respectively (Table 1).

C<sub>1</sub>= Polythene bag, C<sub>2</sub>= Plastic pot container, C<sub>3</sub>= Tin container, C<sub>4</sub>= Cloth bag, M<sub>1</sub>= 8% initial SMC, M<sub>2</sub>= 10% initial SMC, M<sub>3</sub>= 12% initial SMC, CV=Co-efficient of variation and LS= Level of significance, Figures with similar letter(s) or without letter within the column do not differ significantly whereas figures with dissimilar letter(s) differ significantly at 0.05 level of probability by DMRT, \*\* = Significant at 0.01 level of probability.

**Germination percentage:** The effect of storage container showed significantly differed on germination percentage was in 2010 and 2011. In 2010, the germination percentages of seeds stored in polythene bag were 81.33%, 77.11%, 73.44%, 69.66% and 65.00% at 40, 80, 120, 160 and 200 DAS, respectively. The corresponding values for the seed stored in cloth bag were 60.88%, 35.22%, 13.22%, 5.22% and 3.55%, respectively. In 2011, the germination percentages of seeds stored in polythene bag were 81.44%, 78.11%, 74.44%, 71.33% and 67.11% at 40, 80, 120, 160 and 200 DAS, respectively. The corresponding values for seed stored in cloth bag were 60.66%, 36.22%, 14.22%, 6.22% and 4.22%, respectively (Fig. 3).

**Fig 3.** Effect of storage container on germination of shelled groundnut seed at different days after storage in 2010 and 2011.

The result revealed that seeds stored in polythene bag attained significantly higher germination than those in cloth bag. The reason of higher seedling emergence

performance with seeds stored at lower initial moisture content in polythene bag may be due to low internal physiological activities in seeds at low seed moisture content. Alencar *et al.* (2006) and Sucheta *et al.* (2007) reported that soybean seeds viability generally deteriorated with storage duration and deterioration was particularly strong for seed stored with higher (14.8%) than lower (12.8%) initial moisture content.

**Fig 4.** Effect of initial SMC on germination of shelled groundnut seed at different days after storage in 2010 and 2011.

The initial SMC had significant effect on germination percentages of groundnut seeds during the storage period in 2010 and 2011. In 2010, the germination percentage for the seeds stored at 8% initial SMC were 77.50%, 69.33%, 61.16%, 54.25% and 50.08% at 40, 80, 120, 160 and 200 DAS, respectively and those for 12% initial SMC were 73.50%, 62.00%, 53.75%, 43.91% and 38.08%, respectively. In 2011, the germination percentage of seeds kept at 8% initial SMC were 77.75%, 70.33%, 62.16%, 56.83% and

52.83% at 40, 80, 120, 160 and 200 DAS and those for 12% initial SMC were 73.58%, 63.00%, 54.75%, 45.41% and 40.50%, respectively (Fig. 4). Thus, it was noted that the germination percentage decreased with the increase of initial SMC and also with increase storage duration in both the years. The present study revealed that seedling emergence performance

decreased with increase of initial SMC. The reason of higher seed viability at lower initial SMC may be due to low internal physiological activities in seeds (Rahman *et al.*, 2010). Similar decrease of soybean seedling emergence performance with increase of initial SMC was also reported by Sarmin (2009).

C<sub>1</sub>= Polythene bag, C<sub>2</sub>= Plastic pot container, C<sub>3</sub>= Tin container, C<sub>4</sub>= Cloth bag, M<sub>1</sub>= 8% initial SMC, M<sub>2</sub>= 10% initial SMC, M<sub>3</sub>= 12% initial SMC, CV=Co-efficient of variation and LS= Level of significance, Figures with similar letter(s) or without letter within the column do not differ significantly whereas figures with dissimilar letter(s) differ significantly at 0.05 level of probability by DMRT, \*\* = Significant at 0.01 level of probability.

The interaction effect of storage container and initial SMC on germination percentage was statistically significant during the storage period in 2010 and 2011. In 2010, the germination percentage of stored seed at 8% initial SMC in polythene bags were 83.3%, 81.0%, 78.3%, 74.6% and 71.0% at 40, 80, 120, 160 and 200 DAS while those seeds stored at 12% initial SMC in cloth bags were 59.0%, 33.3%, 11.3%, 3.3% and 1.6%, respectively. In 2011, the germination percentage of seeds kept at 8% initial SMC in polythene bags were 83.3%, 82.0%, 79.3%, 77.3% and 74.6% at 40, 80, 120, 160 and 200 DAS while those seeds stored at 12% initial SMC in cloth bags were 58.3%, 34.3%, 12.3%, 4.3% and 2.3%, respectively (Table 2). The result revealed that seeds stored in polythene bag at any of the initial SMC had higher germination percent than those stored in cloth bag.

**Vigour index:** The storage container showed significant effect on vigour index of groundnut seed at each of the observation dates during the storage period in 2010 and 2011. At each observation date it was found that the vigour index decreased with the increase of initial SMC for both the years. In 2010, the vigour indexes of seeds stored in polythene bag were 17.67, 16.26, 15.12, 13.22 and 11.47 at 40, 80, 120, 160 and 200 DAS, respectively. The corresponding values for seed stored in cloth bag were 11.04, 5.12, 1.90, 0.88 and 0.67, respectively. Similarly in 2011, the vigour index of seeds in polythene bag were 10.86, 10.23, 10.028.48 and 7.51 at 40, 80, 120, 160 and 200 DAS respectively. The corresponding values for seed stored in cloth bag were 8.93, 8.32, 7.66, 5.32 and 3.44, respectively (Fig. 5). Karim *et al.* (2005) reported that seeds stored in moisture impervious containers like sealed alluminum foil bag and polythene bag showed superior

germination, vigour and field performance than other containers.

**Fig 5.** Effect of storage container on vigour index of shelled groundnut seed at different days after storage in 2010 and 2011.

**Fig 6.** Effect of initial SMC on vigour index of shelled groundnut seed at different days after storage in 2010 and 2011.

The initial SMC had significant effect on vigour index at each of the observation dates during the storage period in 2010 and 2011. Those seeds stored at 8% initial SMC showed higher vigour index than those stored at 12% initial SMC in all the observation dates for both the years. In 2010, the vigour index of seed stored at 8% initial SMC were 15.99, 13.80, 12.73, 10.28 and 8.91 at 40, 80, 120, 160 and 200 DAS and those at 12% initial SMC were 14.87, 12.66, 10.00, 8.76 and 7.17, respectively. Similarly

in 2011, the vigour index of seed kept at 8% initial SMC were 0.41, 9.73, 9.56, 7.73 and 6.48 at 40, 80, 120, 160 and 180 DAS and those values at 12% initial SMC were 9.74, 9.37, 9.28, 7.12 and 5.86, respectively (Fig 6).

The interaction effect of polythene bag and 8% initial SMC on vigour index was statistically significant at each of the observation dates during the storage period in 2010 and 2011. In 2010, the vigour index of seeds stored at 8% initial SMC in polythene bags were 18.54, 16.92, 16.48,

13.98 and 12.2 at 40, 80, 120, 160 and 200 DAS while those values at 12% initial SMC in cloth bag were 10.5, 4.58, 1.53, 0.55 and 0.32, respectively. Similarly, in 2011 the vigour index of seeds stored at 8% initial SMC in polythene bags were 11.42, 10.41, 10.29, 8.91 and 7.87 at 40, 80, 120, 160 and 200 DAS while those values for cloth bag at 12% initial SMC were 8.63, 7.95, 7.51, 4.84 and 3.16, respectively (Table 3).

C<sub>1</sub>= Polythene bag, C<sub>2</sub>= Plastic pot container, C<sub>3</sub>= Tin container, C<sub>4</sub>= Cloth bag, M<sub>1</sub>= 8% initial SMC, M<sub>2</sub>= 10% initial SMC, M<sub>3</sub>= 12% initial SMC, CV=Co-efficient of variation and LS= Level of significance.

The result concludes that groundnut seed could be stored after shelling with high germination capacity (>80%) for at least 7 months (from rabi to rabi sowing) in polythene bags kept at ambient room conditions.
